# Scaling Web Applications On-Demand in Cloud

Good performance + Cost efficiency

High throughput + low  
response time

High resource  
utilization

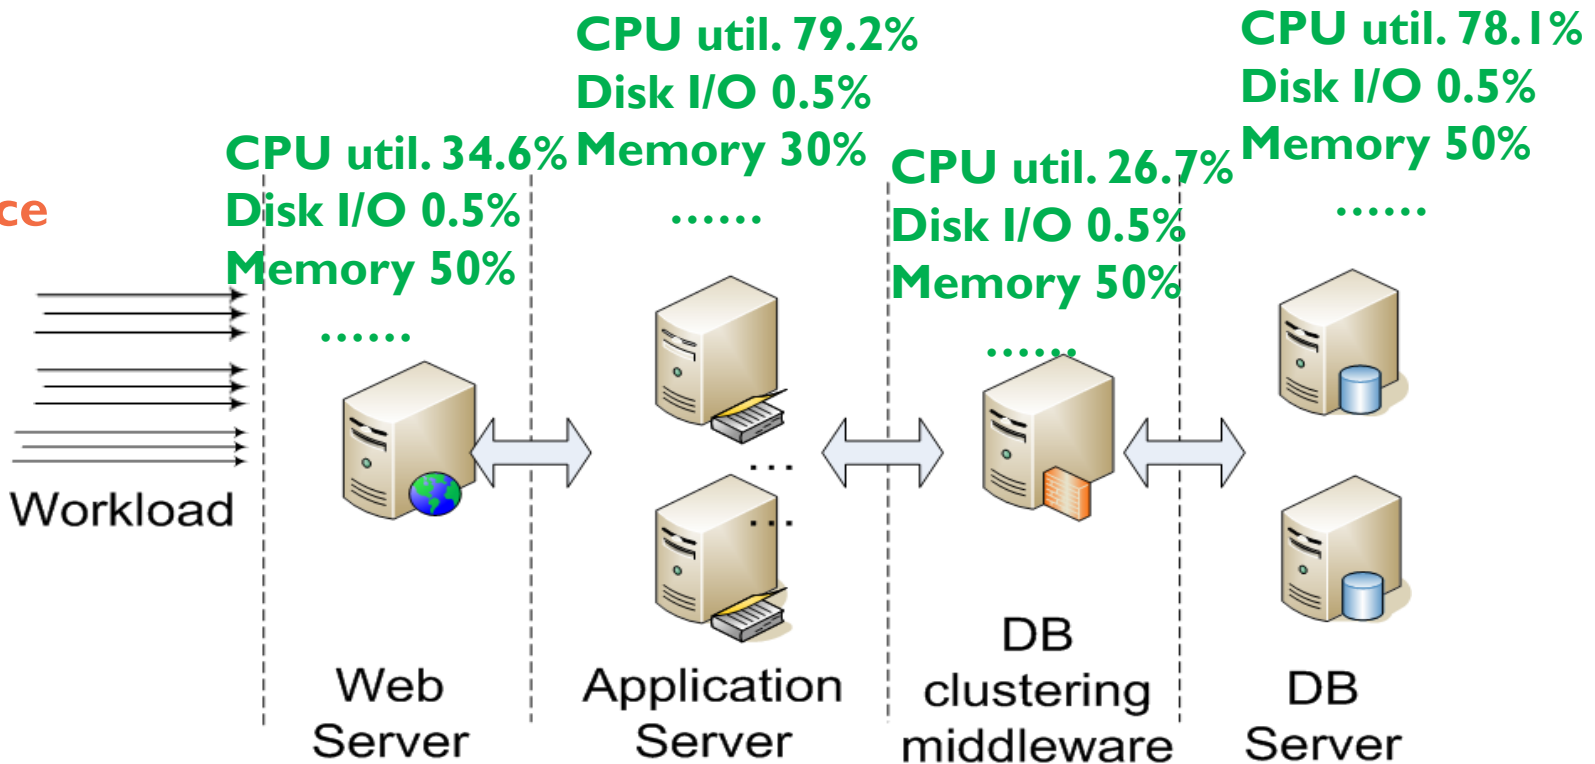

# What If No Bottleneck Was Detected?

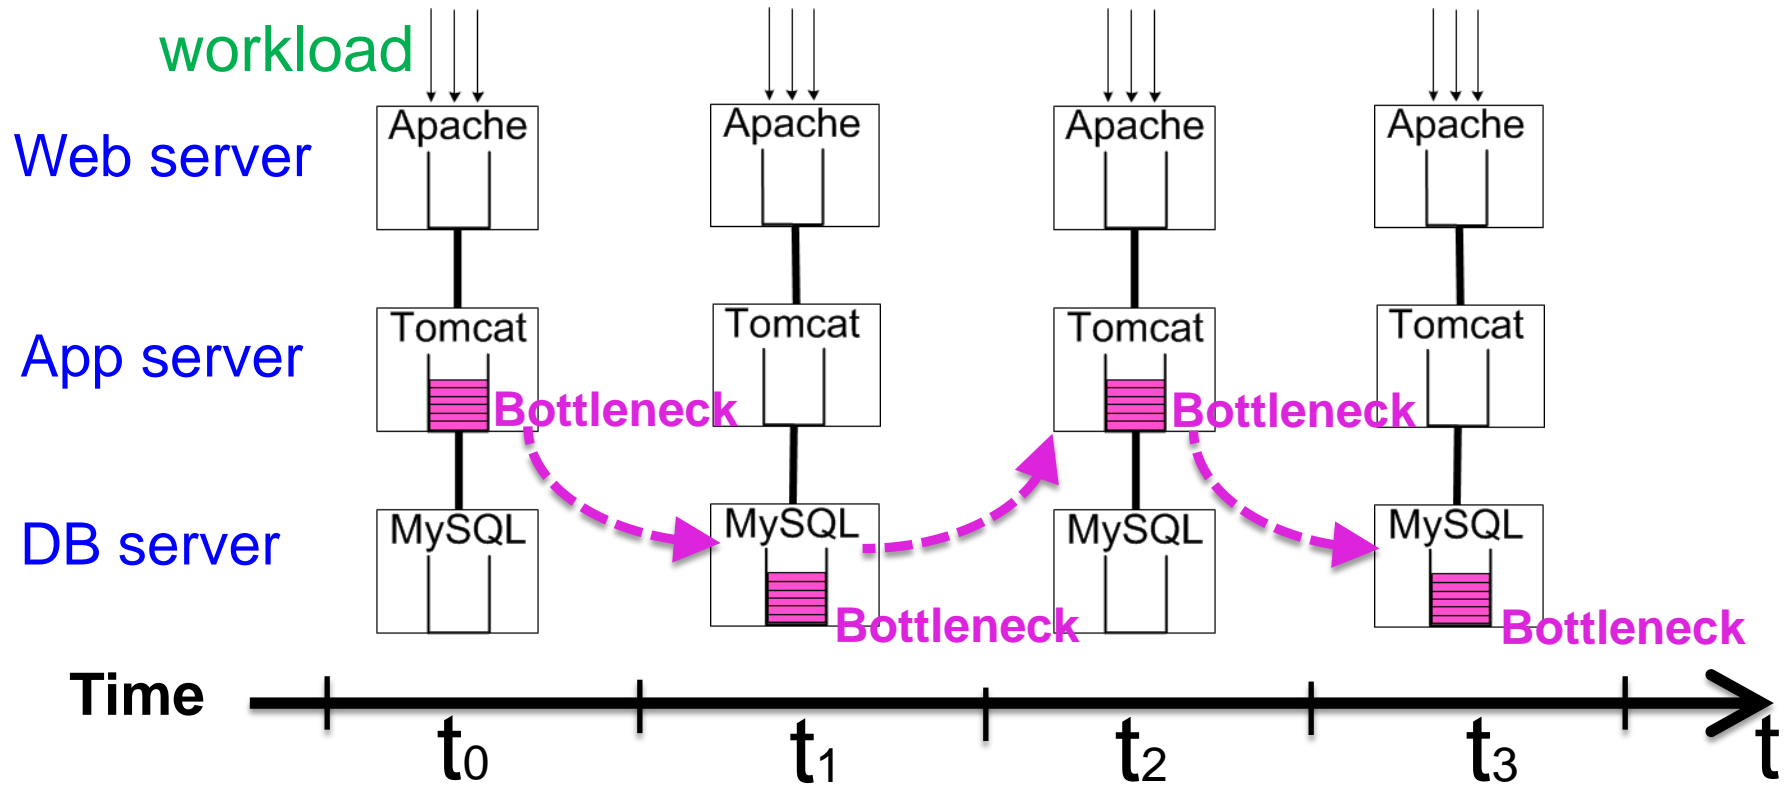

How to scale a web application while no bottleneck is identified?

Bad performance

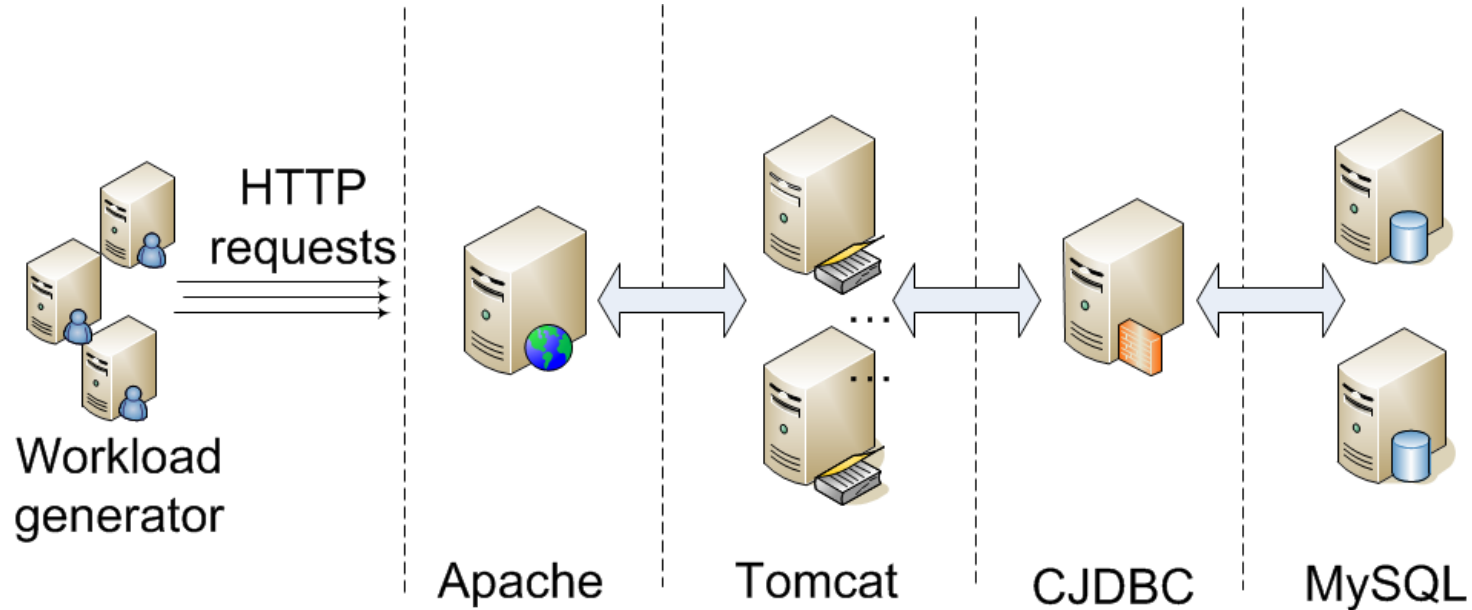

# Rapidly Alternating Bottlenecks

1. Throughput is limited with no saturated resources
2. Duration of each bottleneck is short (e.g.,  $< 100\text{ms}$ )

# Experimental Setup

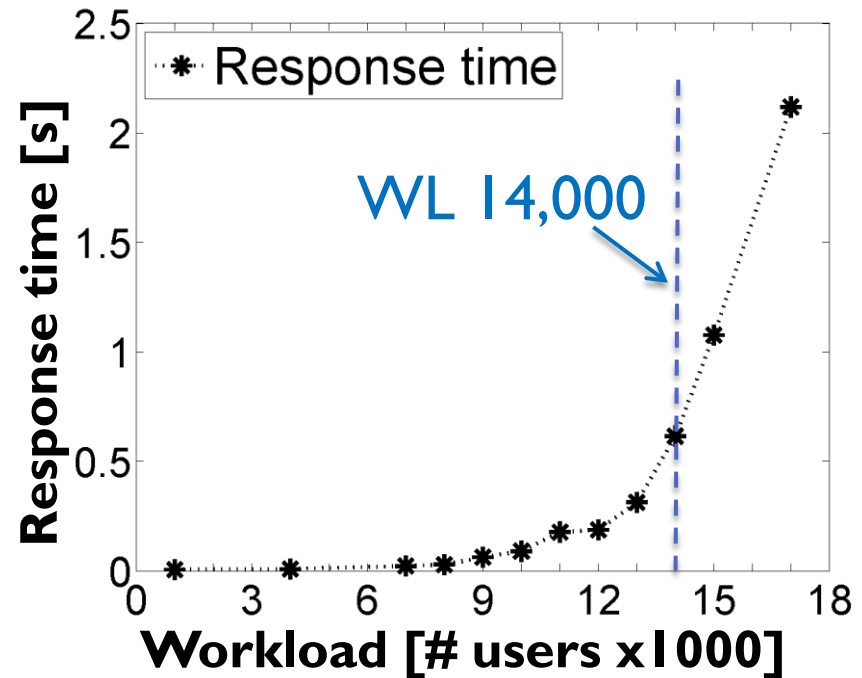

- ❑ RUBBoS benchmark: a bulletin board system like Slashdot
- ❑ 24 web interactions  
**CPU intensive**
- ❑ Workload consists of emulated clients

- ❑ Intel Xeon E5607  
2 quad-core 2.26 GHz  
16 GB memory

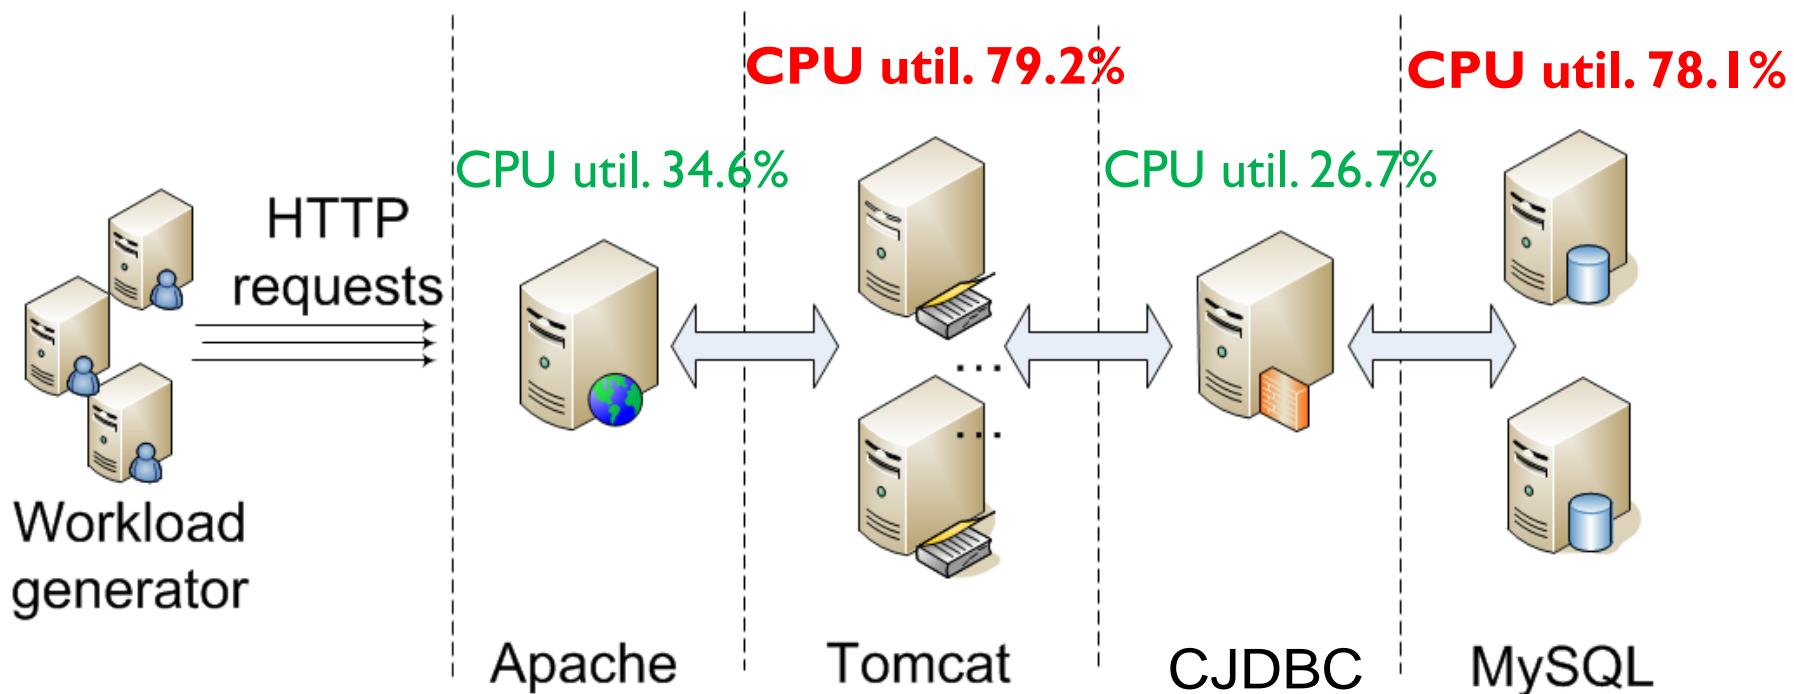

# Motivational Example

- Response time & throughput of a 3-minute benchmark on the 4-tier application with increasing workloads.

# No Obvious Bottleneck is Detected at WL 14,000

- Workload is CPU intensive
  - ◆ Disk I/O utilization (<5%), network I/O utilization (<20%), Memory usage (<40%);

# Rapidly Alternating Bottleneck: Sources and Detection

- **Sources:** We find that other than bursty workload, system environmental conditions:
  - ◆ JVM garbage collection
  - ◆ VM collocation
- **Detection and Visualization:** We implement a fine-grained monitoring method based on **passive network tracing**.
  - ◆ Negligible monitoring overhead for running applications

# Outline

- Introduction & Motivation

- □ Detection and Visualization

  - ◆ Fine-grained load/throughput analysis

- Two Observations of Rapidly Alternating Bottlenecks

  - ◆ JVM garbage collection (JVM GC)

  - ◆ VM collocation

- Conclusion & Future Works

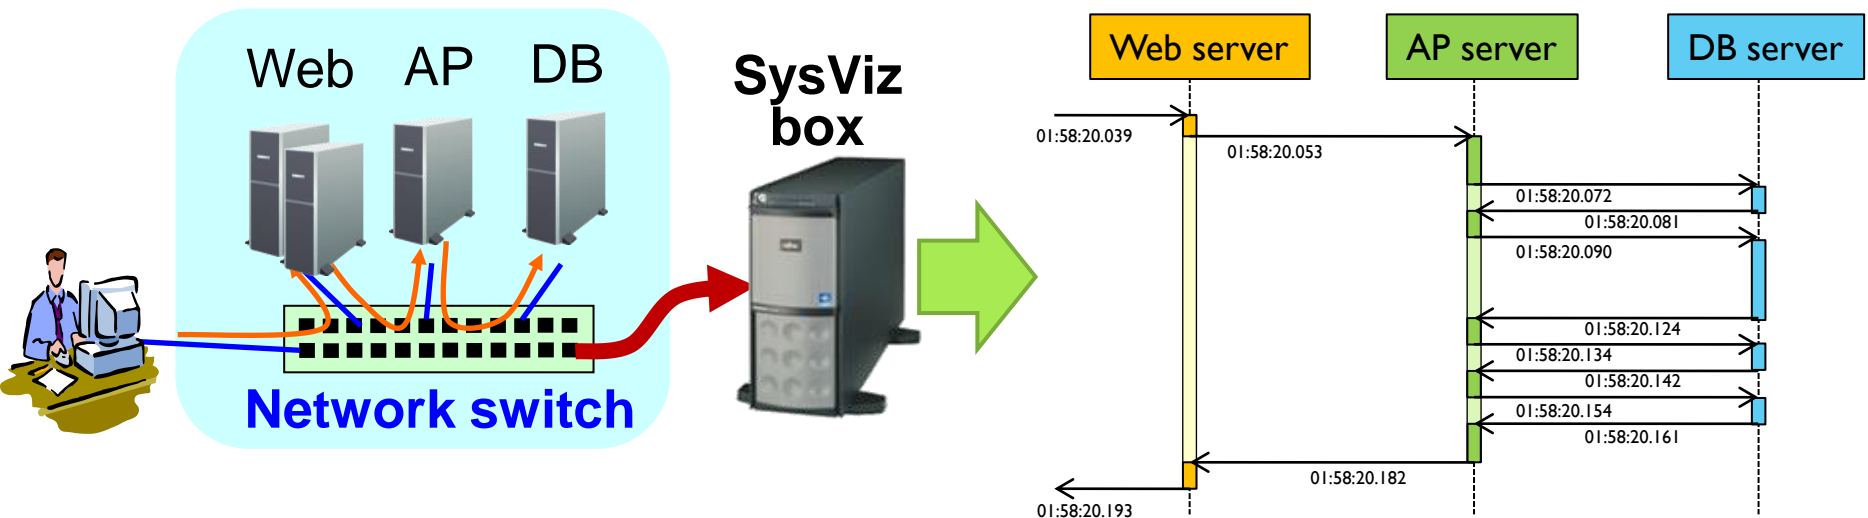

# Two Steps for Detecting Rapidly Alternating bottlenecks

1. Find the participating servers that **present transient bottlenecks(e.g., 50ms)**
2. Check whether the transient bottlenecks of each participating server **occur in an alternating pattern**

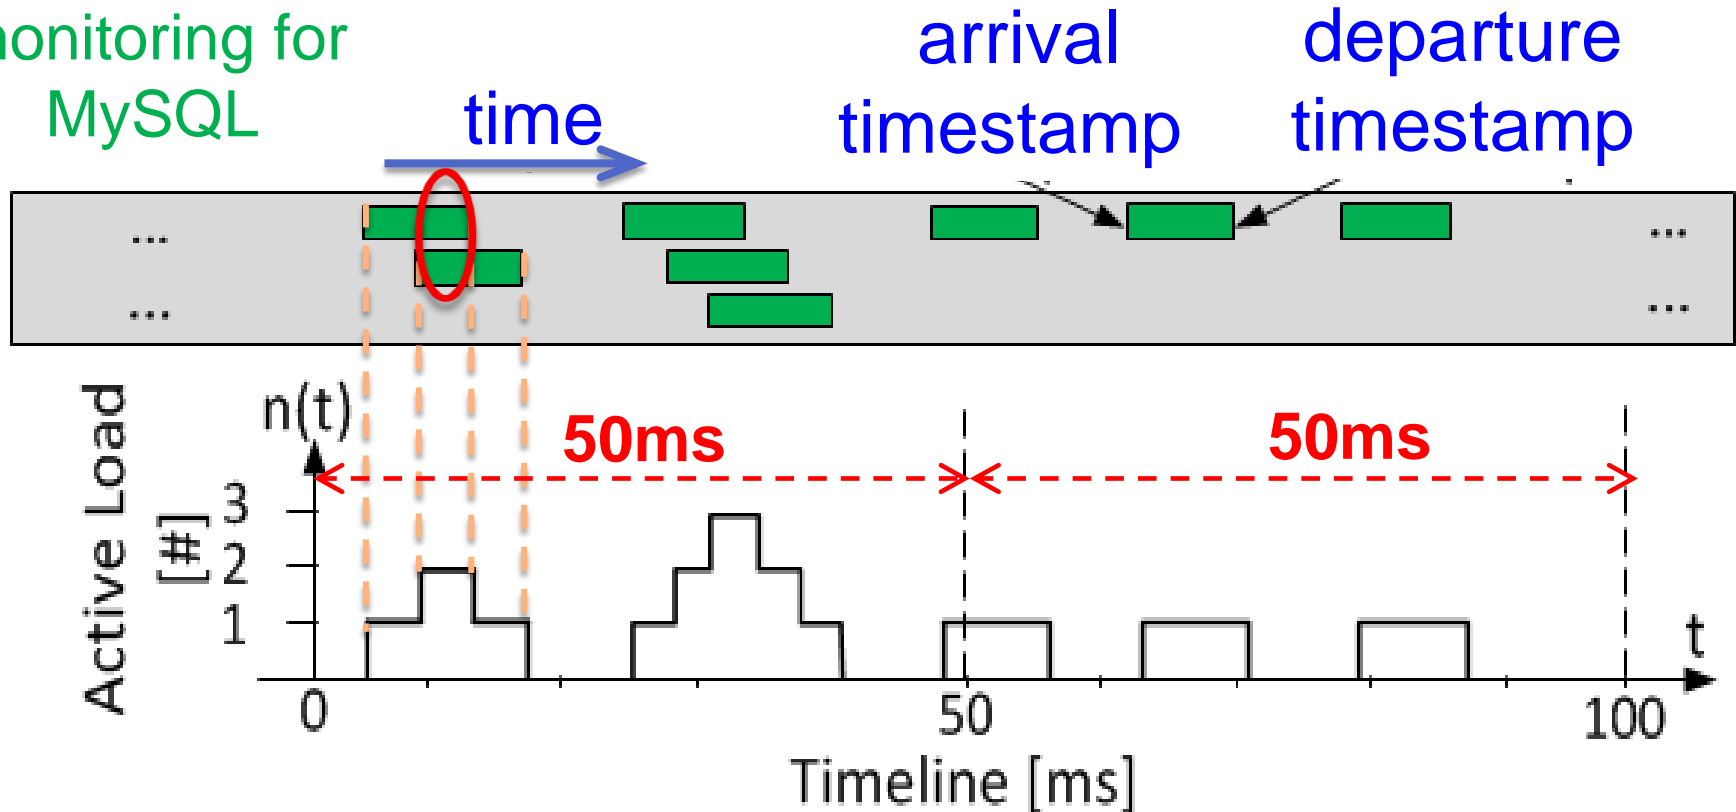

# Passive Network Tracing Infrastructure

- ❑ Collect interaction messages in the system using SysViz to measure fine-grained **active load** and **throughput** on each server.
- ◆ **Active load**: The # of concurrent requests in a server
- ◆ **Throughput**: The # of completed requests of a server

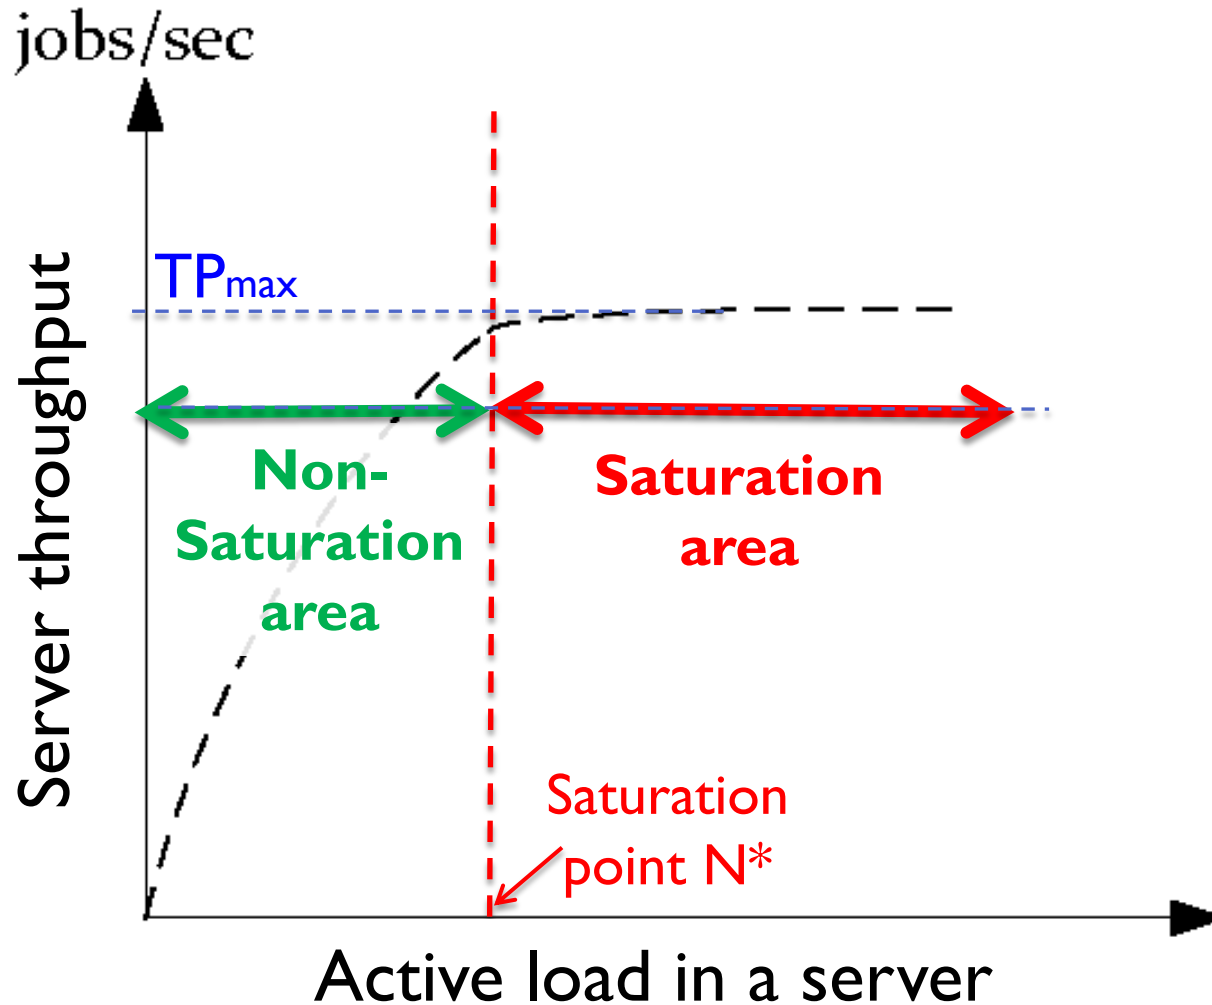

# Fine-Grained Active Load Calculation in a Server

SysViz  
monitoring for  
MySQL

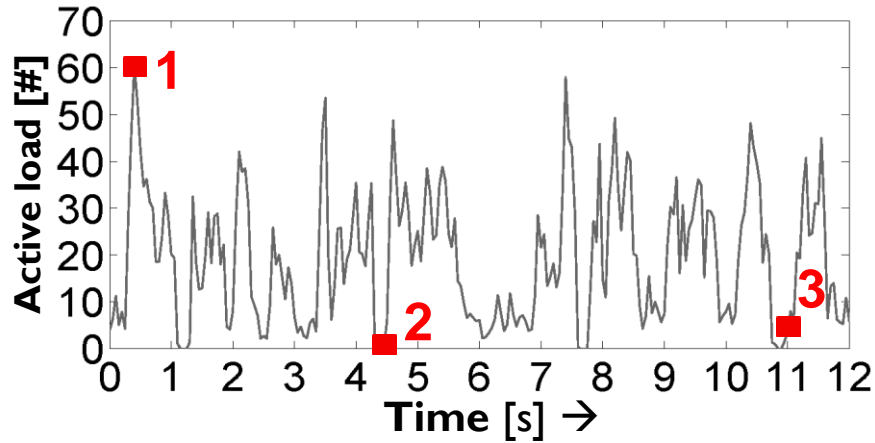

# Active-Load/Throughput Correlation Analysis

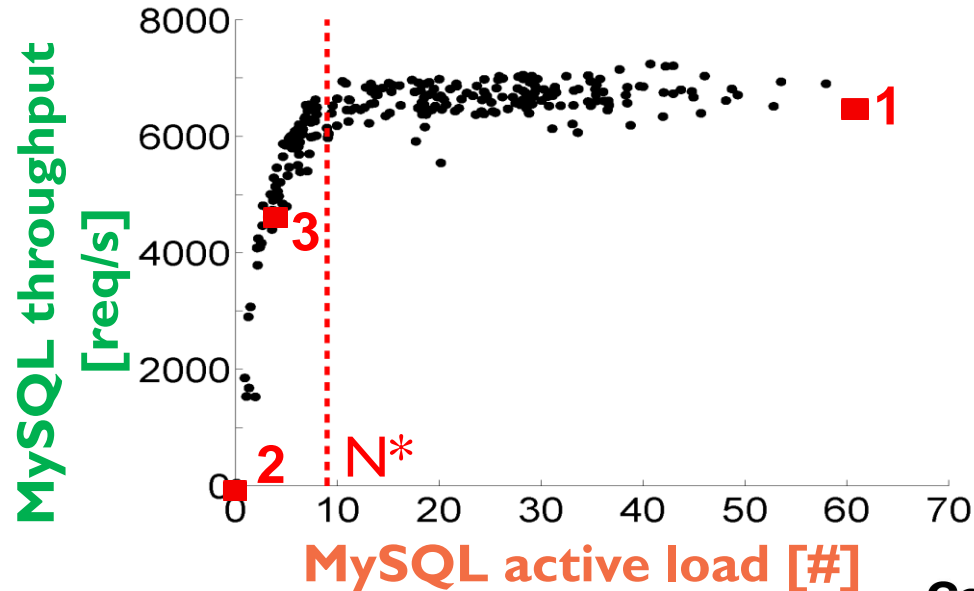

# Active-Load/Throughput Analysis for MySQL at WL 14,000

## MySQL active load (every 50ms)

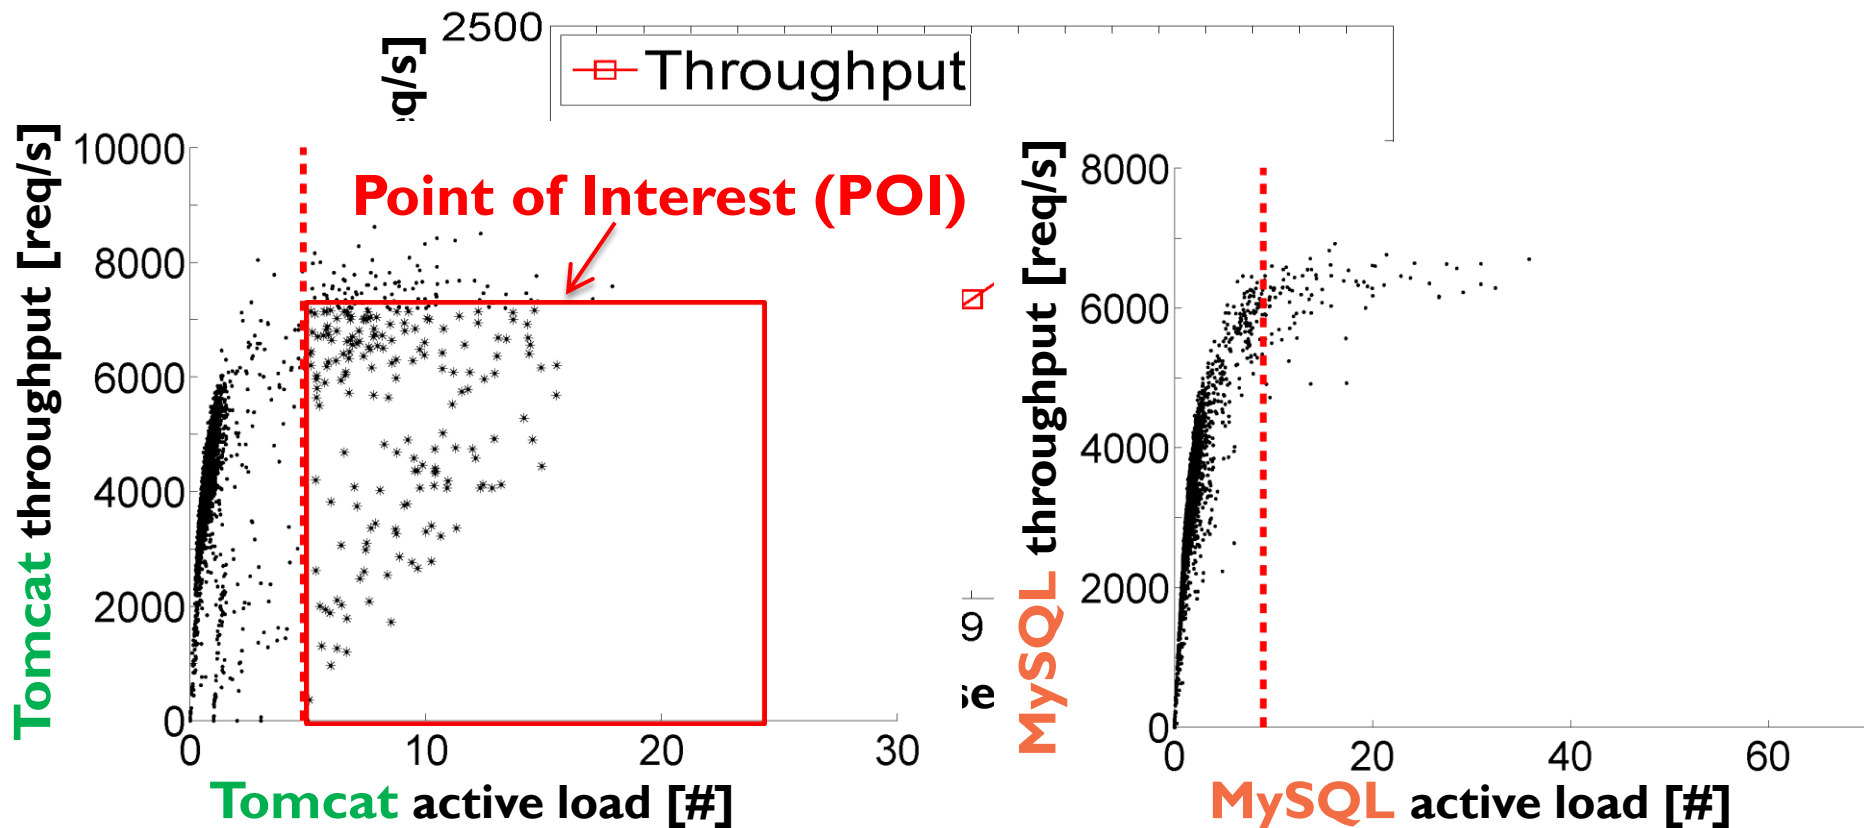

## MySQL throughput (every 50ms)

# Outline

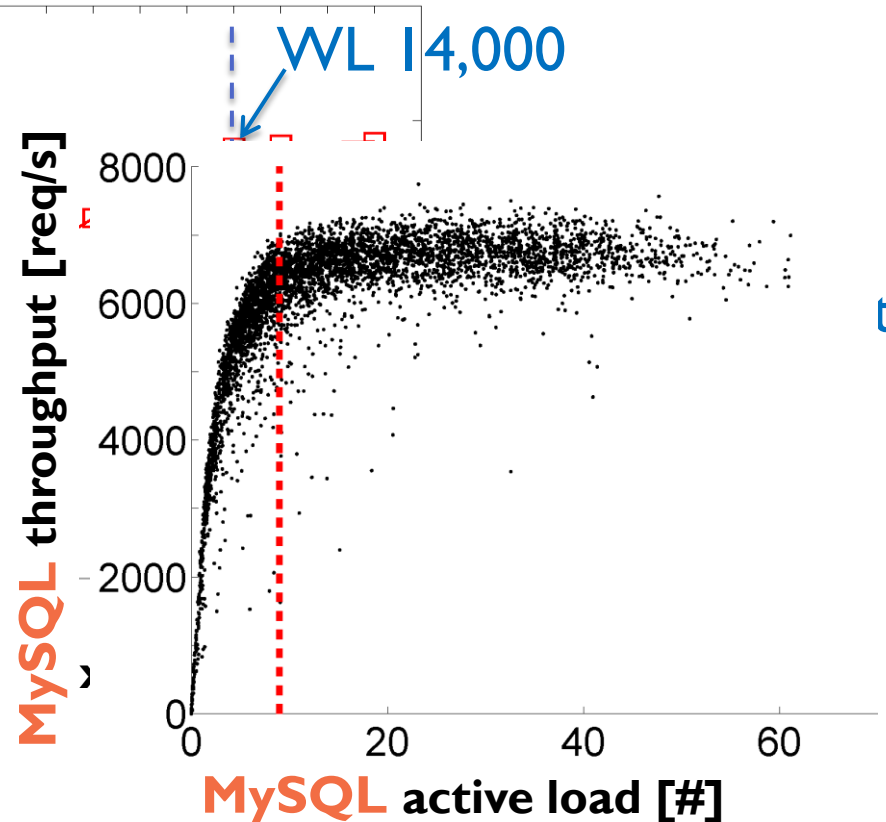

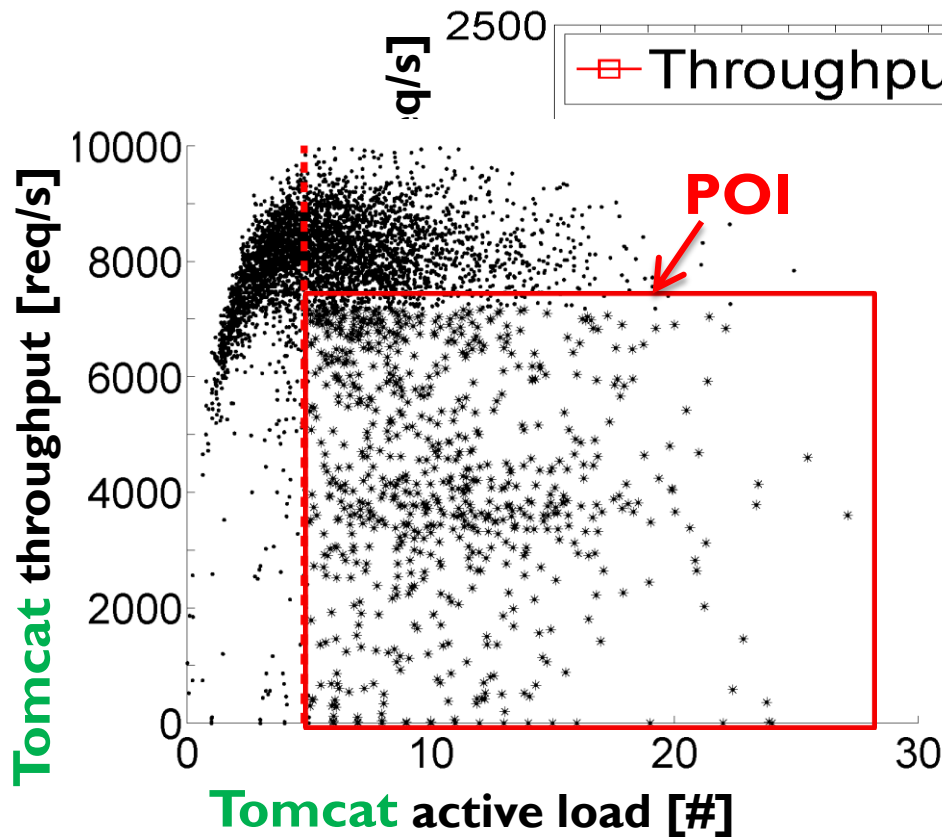

- Introduction & Motivation
- Detection and Visualization
  - ◆ Fine-grained load/throughput analysis
- Two Observations of Rapidly Alternating Bottlenecks
  - ➔◆ JVM garbage collection (JVM GC)
  - ◆ VM collocation
- Conclusion & Future Works

# Active-Load/Throughput Analysis at Workload 7,000

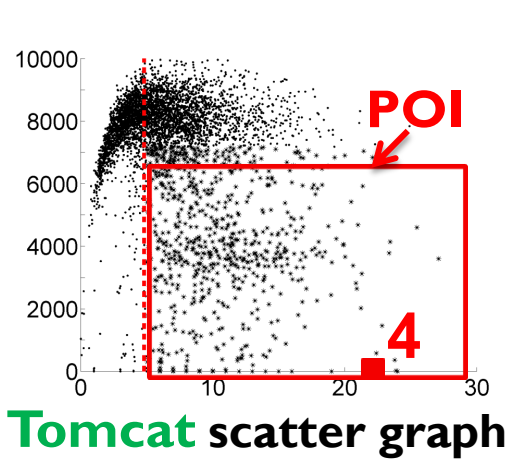

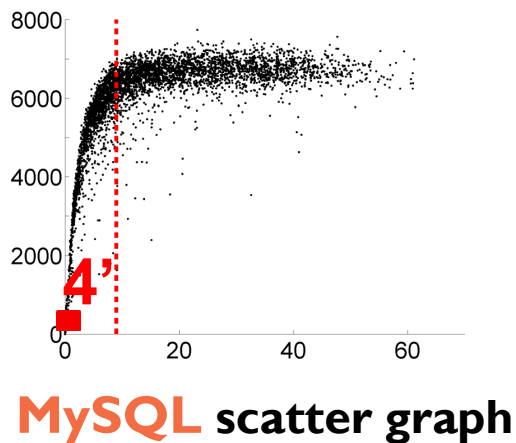

# Active-Load/Throughput Analysis at Workload 14,000

# Timeline Analysis at Workload 14,000

# Timeline Analysis at Workload 14,000 (Cont.)

# Correlation Analysis of Rapidly Alternating Bottlenecks

Correlation coefficient:  $-0.42$ , negative correlation suggests rapidly alternating bottleneck.

# Outline

- Introduction & Motivation
- Detection and Visualization
  - ◆ Fine-grained load/throughput analysis
- Two Observations of Rapidly Alternating Bottlenecks
  - ◆ JVM garbage collection (JVM GC)
  - ◆ VM collocation
- ➡ □ Conclusion & Future Works

# Conclusion & Future Work

- ❑ Rapidly alternating bottlenecks can cause **non-trivial performance loss** in an n-tier system.
- ❑ We proposed a rapidly alternating bottleneck detection and visualization method through **fine-grained active-load/throughput analysis**
- ❑ Ongoing work: more analysis of **different types of workloads** and **more system factors** that cause rapidly alternating bottlenecks.

# Thank You. Any Questions?
